OPPENAUER OXIDATION

It is a useful method for oxidising secondary alcohols into ketones. This reaction is opposite to that of Meerwein-Ponndorf-Verly reduction.

Alcohol gets oxidised by using aluminium isopropoxide in presence of excess acetone. This oxidation is highly selective and does not occur in case of amines & sulphides. Primary alcohols do not undergo oppenauer oxidation as they show competition with aldol condensation of aldehyde products.

Mechanism

Step 1: Alcohol forms co-ordination complex with Aluminium.

Step 2: Complex gets deprotonated by an alkoxide ion to produce an intermediate.

Step 3: Both the acetone and the alcohol gets bound to the aluminium.

Step 4: Aluminium catalyses hydride shift from α -carbon of alcohol to the carbonyl carbon of acetone. There occurs a formation of six-membered transition state.

Step 5: Finally, ketone is formed after hydride transfer.

DAKIN REACTION

In Dakin reaction, phenols can be prepared from aryl aldehydes or arylketones by oxidation with hydrogen peroxide in the presence of a base. Basic requirement is that an -OH or -NH₂ group must be present at ortho or para position. Aryl formate or alkanoate are formed as an intermediate which gets saponified to give substituted phenol product.

$$\begin{array}{c|c} & & & \\ \hline & & \\ OH & & \\ \hline \end{array} \begin{array}{c} & & \\ & & \\ OH & \\ \end{array} \begin{array}{c} & & \\ & & \\ OH & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ & & \\ \end{array} \begin{array}{c} & & \\ \end{array} \begin{array}{c} & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ \end{array} \begin{array}{c} & & \\ \end{array} \begin{array}{c} & & \\ & & \\ \end{array} \begin{array}{c} & & \\ & & \\ \end{array} \begin{array}{c} & & \\ \end{array} \begin{array}{c} & & \\ & & \\ \end{array} \begin{array}{c} & & \\$$

Overall, the carbonyl group is oxidised and the hydrogen peroxide is reduced. This reaction is closely related to Baeyer-Villiger oxidation.

Mechanism: Reaction starts with nucleophillic addition of hydroperoxide anion to the carbonyl carbon & forms a tetrahedral intermediate. Intermediate then breaks down to cause 1,2 aryl migration, hydroxide elimination & formation of phenyl ester which is then hydrolysed to form the product.
